INDEX0

PRE-SEED · NOVEMBER 2026 · INDEX0 RESEARCH LABS

Verification before merge. A self-hosted, four-tier review loop (Architect, Developer, Critic, QA) where the QA tier **executes the candidate code** against the repository's own test suite in a network-isolated container. The verdict is an exit code, not a model's opinion of the diff.

Problem

AI coding tools produce plausible code that passes the wrong tests. Every existing review layer (Copilot, Cursor, Qodo, OpenHands) reports findings or scores; none hands a regulated customer a replayable artifact proving the fix ran. AI-assisted teams ship 3–4× the code with 10× the security findings, and auditors now ask for evidence.

Product

- Developer output is whole files (models are bad at hunk arithmetic); the unified diff is derived by us.
- Critic review is advisory-only: `request_changes` with no critical/error finding is auto-upgraded to `approve`.
- QA copies the repo into a container with `--network none`, writes the candidate, runs `npm test`, reports exit code and counts the runner printed.
- Candidate edits to test files are dropped, so the assertions that decide the verdict are always the repository's own.
- Every cycle is hash-chained and attributable (GNAP).

Proof (we audited ourselves first)

- **15 of 36** claimed capabilities verifiable today — listed line by line in `PROOF_STATUS.md`, shipped in the repo.
- **0 of 3** published benchmarks. The old 96.2% SWE-bench / 92% AiderBench numbers were unverified and removed.
- **30/30** orchestrator tests, 14 sandbox-manager, full monorepo build, all green in CI.
- Six committed end-to-end runs: `qa_verified`, exit 0. Three on a free model route, 1.2–1.7 s each.

Market

Secure code review platforms: $1.22B (2025) → $2.44B (2030), 14.9% a year (Mordor Intelligence). Our slice: 2,500 orgs × 500 developers × $360 = $450M. Buyer: 200–5,000 developers in regulated organisations (finance, healthcare, gov) already on cloud contracts, priced out of enterprise-tier review tools.

Ask

$750K pre-seed over 18 months to turn a working loop into three paid pilots whose replayable artifacts survive a real audit. Use of funds: two hires (sandbox infrastructure, security), founder-led GTM with three design partners, and SOC 2 Type I. Inference runs on the customer's model contract, so our COGS look like software.

Live demo

`./demo/run-demo.sh` — one command, ~7 s warm, no Azure, no paid API. The transcript on slide 7 is the output of a run minutes before the deck was exported.
