PRE-SEED · NOVEMBER 2026 · INDEX0 RESEARCH LABS

INDEX0

The verification layer for AI-written code.

A working gate. It runs your tests before it says yes.

demo: 7 seconds, free model route

AI made code cheap. Proving it correct did not.

The bottleneck moved from writing to verifying.

10×

more security findings from AI-assisted developers, who also wrote 3–4× more code.

45%

of AI-generated samples introduced an OWASP Top 10 flaw — flat across model generations.

66%

of developers say the frustration is code that is “almost right, but not quite”.

✓	Lint passes	CHECKED
✓	Types check	CHECKED
✓	Reviewer approves	CHECKED
✗	Tests executed	ASSUMED

Three of four is how a plausible patch reaches production.

Apiiro, Sep 2025 · Veracode, Jul 2025 · Stack Overflow Developer Survey 2025

A gate, not another generator.

Four tiers. The last one runs the code.

Architect

Turns the objective into invariants that can actually be violated.

Developer

Edits the real files. Whole contents, no hunk arithmetic.

Critic

Adversarial review. Only critical findings can block a merge.

QA — executes it

Runs the candidate against your suite in a sealed container, no network.

The verdict is an exit code, not an opinion of the diff.

Four tiers, one verdict.

This is a real run, not a mock.

```
$ ./demo/run-demo.sh
==> gateway · free route, no database
==> sandbox · provider=docker
==> review cycle

status      qa_verified
iterations  1
critic      approve
tests       3 passed / 0 failed  1664 ms
sandbox     live_microvm (exit 0)

history
  architect   plan_proposal
  developer   implementation
  critic      review_verdict   approve
  qa          test_result      passed
```

demo/runs/20261031T041126Z · committed with the code

QA copies the repository into a container, writes the candidate over the copy, drops any edit that lands on a test file, and runs **your** suite with no egress.

```
--- a/src/math.js
+++ b/src/math.js
 export function divide(n, d) {
+  if (d === 0) {
+    throw new RangeError('division by zero');
+  }
   return n / d;
 }
```

Read-only source mount · --network none · exit code 0 required for a pass

Six things that are hard to copy.

Each one was paid for by a mistake we found in our own code.

Whole files, not hunks

We take file contents, derive the diff ourselves and reject corrupt patches.

Advisory critic

“Request changes” without a critical finding is upgraded to approve. No invented requirements.

Test-edit guard

Candidate writes to test paths are dropped before the suite runs.

Network-isolated

No egress during verification. Source mounted read-only.

Own keys

OpenAI, Anthropic, Azure, Bedrock, vLLM — or an air-gapped endpoint.

Hash-chained

Every cycle is signed and attributable to a key, not a log line.

The test-edit guard exists because a Gemini run edited the test that judged it.

What ships today.

Not a roadmap. The repository is public.

CLI + TUI	Terminal agent, worktree isolation, GitHub device-flow login.
4-tier loop	LangGraph. 30/30 tests green.
Sandbox	Docker or Firecracker/E2B microVMs, `--network none`.
Routing	LiteLLM proxy. Any OpenAI-compatible backend.
Audit	GNAP signing, hash-chained cycles, replayable artifacts.

```
{
  "status": "qa_verified",
  "iterations": 1,
  "critic": "approve",
  "tests": { "passed": 3, "failed": 0 },
  "sandbox": { "exit_code": 0 },
  "diff_sha256": "9f2c…"
}
```

The artifact a reviewer keeps.

15 of 36 claimed capabilities are verifiable today — PROOF_STATUS.md, in the repo.

Where the gate pays for itself.

Every one of these is a patch that looks right.

Security fixes

Fixes that compile, pass lint and open a CVE anyway.

Refactors

Mechanical changes where “looks right” is not evidence.

Dependency bumps

Upgrades that break call sites nobody opened.

Almost-right code

The 45% of AI output that is plausible, not correct.

The expensive bug is the one that passed review.

Veracode 2025 GenAI Code Security Report · Stack Overflow Developer Survey 2025

The buyer changed from tooling to compliance.

Sovereignty is now a scored procurement criterion, not a preference.

Regulation

EU DORA, the EU Cloud Sovereignty Framework and India DPDP now ask where the code and the model ran.

Adoption

90% of enterprise engineers will use AI code assistants by 2028. The review queue grows either way.

Volume

3–4× more code and 10× more findings, reviewed by the same number of senior engineers.

Compliance budgets already exist. Developer-tool budgets get cut.

European Commission, 20 Oct 2025 · India MeitY, 13 Nov 2025 · Gartner, Feb 2026

The budget is real. Here is the math.

Top-down and bottom-up, and we quote the low end.

2,500	regulated organisations
× 500	developers each
× $360	per developer, per year

$450M we can sell into

One house, two published points, 14.9% a year. Our slice is the regulated half: 37% of the category.

Mordor Intelligence, Secure Code Review Platforms Market: $1.22B (2025) → $2.44B (2030) · bottom-up is ours, at $30/developer/month

We charge for the gate, not the tokens.

Inference runs on the customer’s contract, so gross margin is software.

$30 / dev / mo	The default seat. Every merge passes through the gate.
$0.40 / cycle	Metered CI usage above the seat allowance.
$120k / year	Enterprise: SSO, audit export, on-prem sandbox, support.

ONE 500-DEVELOPER ACCOUNT

$180k

a year, at $30 per seat

Inference runs on their contract. Our cost is compute we already run, so gross margin tracks software.

Pricing hypothesis. Three design partners are testing it now; nothing here is booked.

Everyone reviews. Nobody hands you the receipt.

The gap is execution plus evidence, not better suggestions.

TOOL	CATEGORY	RUNS YOUR TESTS	SHIPS AN EVIDENCE ARTIFACT
GitHub Copilot	IDE and PR review	No	No
Cursor	AI editor	No	No
Qodo	Test generation	Generates tests	No
OpenHands	Agent platform	Yes	No
INDEX0	Verification gate	**Yes, sealed**	**Yes, hash-chained**

Public product documentation, November 2026. They can bundle this; we are betting they will not run it in the customer’s tenant.

We audited our own claims and deleted what we could not reproduce.

The first thing we verified was ourselves.

15/36

claimed capabilities verifiable today, listed line by line in **PROOF_STATUS.md**.

0

published benchmarks. The old 96.2% SWE-bench and 92% AiderBench numbers were unverified and removed.

30/30

orchestrator tests green, plus 14 sandbox-manager and the full monorepo build.

6

committed end-to-end runs, `qa_verified` and exit 0. Three on a free model route.

> “The first thing we verified was ourselves.”

No revenue. No users. That is precisely what this round is for.

One founder, one working product, no revenue.

The proof above is the CV.

Darion Dev

FOUNDER

Built the four-tier loop, the sandbox and the CLI — 60 commits in this repository.

Wrote the audit that removed our own benchmark claims.

Ships a demo that runs on a free model route, so anyone can reproduce it.

The round buys

A founding engineer for sandbox and infrastructure.

And a security engineer

To take us through SOC 2 Type I before the third pilot signs.

Two people cannot pass enterprise procurement alone. That is what the money is for.

Eighteen months to three paid pilots.

Pre-seed, priced today.

$750K pre-seed

Engineering
Two hires: sandbox/infra, security.

Go-to-market
Founder-led, three design partners.

Compliance
SOC 2 Type I, external pen test.

3
paid pilots

$300k

SOC 2
Type I

...and one evidence format the buyers agree on.

Own-keys inference keeps gross margin in software. Our burn is two salaries and compute.

The five things that can kill us.

Stated plainly, because you will find them anyway.

01 — Bundling	**Verification is a feature, not a company.** GitHub, Cursor and Qodo can bundle review-plus-tests into seats they already own.
02 — No urgency	**No forcing function.** Audit-ready evidence is nice-to-have until an auditor demands it.
03 — Procurement	**Two people cannot pass enterprise procurement.** SOC 2, pen tests and 9–18 month cycles can outlast the runway.
04 — Credibility	**We shipped bugs we now sell against.** An OTP bypass, injectable telemetry and an offline approval path — all fixed and pinned by tests.
05 — Blind	**Own-keys means no telemetry.** No usage data, no expansion signal, no ROI proof for a board.

Every mitigation is in pitch/README.md, next to the twelve questions investors ask.
